

Similarity Search with Word Embeddings

Runner Java Application Overview

The Java app. designed to read a file containing words and their corresponding 50-dimensional embeddings. An application that allows a user to compare a word against all the 59,602-word embeddings provided in a text file, then creates output a file containing the most similar words and their similarity scores.

How It Works

- An application that allows a user to compare a word against all the 59,602-word embeddings provided in a text file.
- When it works for “File Parsing”, the java application reads a file line by line. Each line contains a word followed by 50 numerical values (the embeddings). The processing of words is case-insensitive.
- Printing Data: User should enter the path for the output file. The Java application creates the file and prints all the words and their embeddings which are containing the most similar words and their similarity scores into the \output.txt file.

How to Use

- From console at file directory: D:\eclipse-workspace\Project\bin> java ie.atu.sw.Runner then navigate through console options.
- Enter the path to the embeddings file. For example: D:\word-embeddings.txt
- Enter the word to compare.
- Enter the example output file size. For example: 10.
- Enter the path for the output file. For example: D:\output.txt. Printing similar words and embeddings with their similarity scores.
